

Final Project : SAMBA File Server

Table of Content:

1. Introduction
2. Step by Step installing SAMBA
 - Pre-Requisites
 - Installing SAMBA on Ubuntu
 - Configuration of SAMBA
 - Running SAMBA
3. Final Quotes

Introduction:

SAMBA is an open source software that allows the user share files between linux/unix machines and Windows devices. However , SAMBA also works with MacOS Devices following a proper configuration. Today , we are going to focus how to set-up SAMBA and run it on a Local Area Network as a file server.

Step by Step Installing SAMBA.

```
[global]
    workgroup = SAMBA
    security = user

    passdb backend = tdbsam

    printing = cups
    printcap name = cups
    load printers = yes
    cups options = raw

    min protocol = SMB2
[homes]
    comment = Home Directories
    valid users = %S, %D%w%S
    browseable = No
    read only = No
    inherit acls = Yes

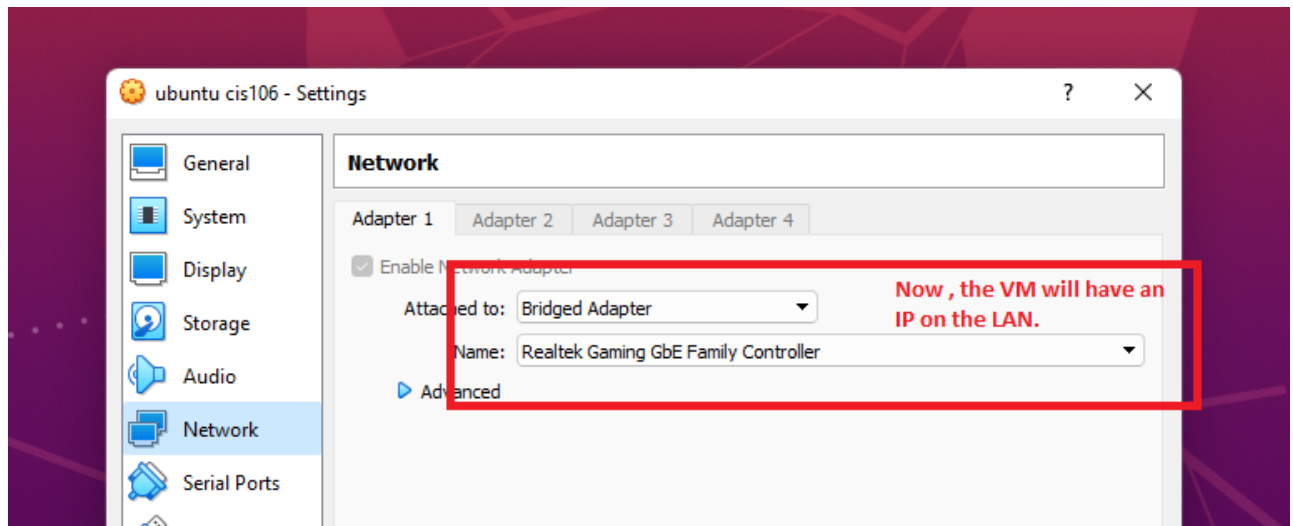

[printers]
    comment = All Printers
    path = /var/tmp
    printable = Yes
    create mask = 0600
    browseable = No

[print$]
    comment = Printer Drivers
    path = /var/lib/samba/drivers
    write list = root
    create mask = 0664
    directory mask = 0775
```

The process of installation of SAMBA is not the hardest but takes its time. It has many configurations to implement devices such as printers. We are going to focus on a simple file server.

Pre-Requisites

- Configuration of the Hypervisor. If you are running Linux on a Virtual Machine , this configuration is mandatory. A Virtual machine default configuration uses internet provided by the host machine. However , in order to make Samba run properly , our virtual machine must have its own ip provided by the router.

Installing SAMBA on Linux Ubuntu 20.04

1. We must install SAMBA and all its dependencies using the following command. `sudo apt install samba`

```
student@student-VirtualBox:~$ sudo apt install samba
[sudo] password for student:
Reading package lists... Done
Building dependency tree
Reading state information... Done
samba is already the newest version (2:4.13.14+dfsg-0ubuntu0.20.04.4).
```

1. Check the status of the Samba Service using the following command. `systemctl status smbd`

```
student@student-VirtualBox:~$ systemctl status smbd
● smbd.service - Samba SMB Daemon
   Loaded: loaded (/lib/systemd/system/smbd.service; enabled; vendor preset: enabled)
   Active: active (running) since Sat 2021-12-18 11:16:09 EST; 3h 13min ago
     Docs: man:smbd(8)
           man:samba(7)
           man:smb.conf(5)
  Main PID: 1906 (smbd)
```

1. Set up Samba to work on your Local Area Network.

- The location of the configuration file of samba is located in `/etc/samba/smb.conf`. We are going to create a file from zero saving the first one as a backup. Type in the terminal: `sudo mv /etc/samba/smb.conf /etc/samba/smb.conf.bak`. It is important to use "sudo" at the beginning because of the permissions of the folder. The command is going to take the original samba configuration file and keep it with a different name.

```
student@student-VirtualBox:~$ ls /etc/samba/
gdbcommands  q  shares.conf  smb.conf  smb.conf.bak  t1s
student@student-VirtualBox:~$
```

- Then, It is important to stop the samba service because it does not have a configuration file. `sudo systemctl stop smbd`. Use `sudo systemctl status smbd` to check if the service is

stopped.

```
student@student-VirtualBox:~$ sudo systemctl stop smbd
[sudo] password for student:
student@student-VirtualBox:~$ sudo systemctl status smbd
● smbd.service - Samba SMB Daemon
   Loaded: loaded (/lib/systemd/system/smbd.service; enabled; vendor p
   Active: inactive (dead) since Sat 2021-12-18 15:18:30 EST; 3s ago
     Docs: man:smbd(8)
           man:samba(7)
           man:smb.conf(5)
  Process: 1906 ExecStart=/usr/sbin/smbd --foreground --no-process-pro
```

- Using a text editor (in this case , we are going to use "nano") create a new "smb.conf" file. `sudo nano /etc/samba/smb.conf`. The file must contain two sections: "global" and "shares". Type the following:

```
[global] server string = Final Project Server workgroup = WORKGROUP security = user
map to guest = Bad User name resolve order = bcast host include =
/etc/samba/shares.conf
```

The most important thing here is the "workgroup". Here you must type the name of the Local Area Network you want samba running. in this case , the workgroup is going to be the default one "WORKGROUP".

```
GNU nano 4.8 /etc/samba/smb.conf
[global]
server string = Final Project Server
workgroup = WORKGROUP
security = user
map to guest = Bad User
name resolve order = bcast host
include = /etc/samba/shares.conf
```

The last line "Include" is going to let me use two different files to organize my global parameters and my share's parameters.

- Now , we have to create the "shares.conf" which is the file that is going to complement the first one. `sudo nano /etc/samba/shares.conf`. Here we must type the following:

```
[final-project-files] path = /home/student/Desktop/ShareableFolder/public force user =
smbuser force group = smbgroup create mask = 0664 force create mode = 0664
directory mask = 0775 force directory mode = 0775 public = yes writable = yes [final-
project-protected-files] path = /home/student/Desktop/ShareableFolder/protected force
user = smbuser force group = smbgroup create mask = 0664 force create mode = 0664
directory mask = 0775 force directory mode = 0775 public = yes writable = no
```

This is an example of a protected folder and a public folder. The only difference between them is "writable" value.

In "path" you are going to type the path of the directory you want to share. "Force user/group" this is going to be defined later. The following lines are going to be the permissions. It is important to enter

the same numbers because windows and linux read permissions in different ways. This is going to solve many compatibility issues.

Once those files are created , save them.

- Now, we have to create the "group" and the "user". Use the following commands:
 - `sudo groupadd --system smbgroup`
 - `sudo useradd --system --no-create-home --group smbgroup -s /bin/false smbuser'`

It is important that you enter the same values for group and user that you entered previously.

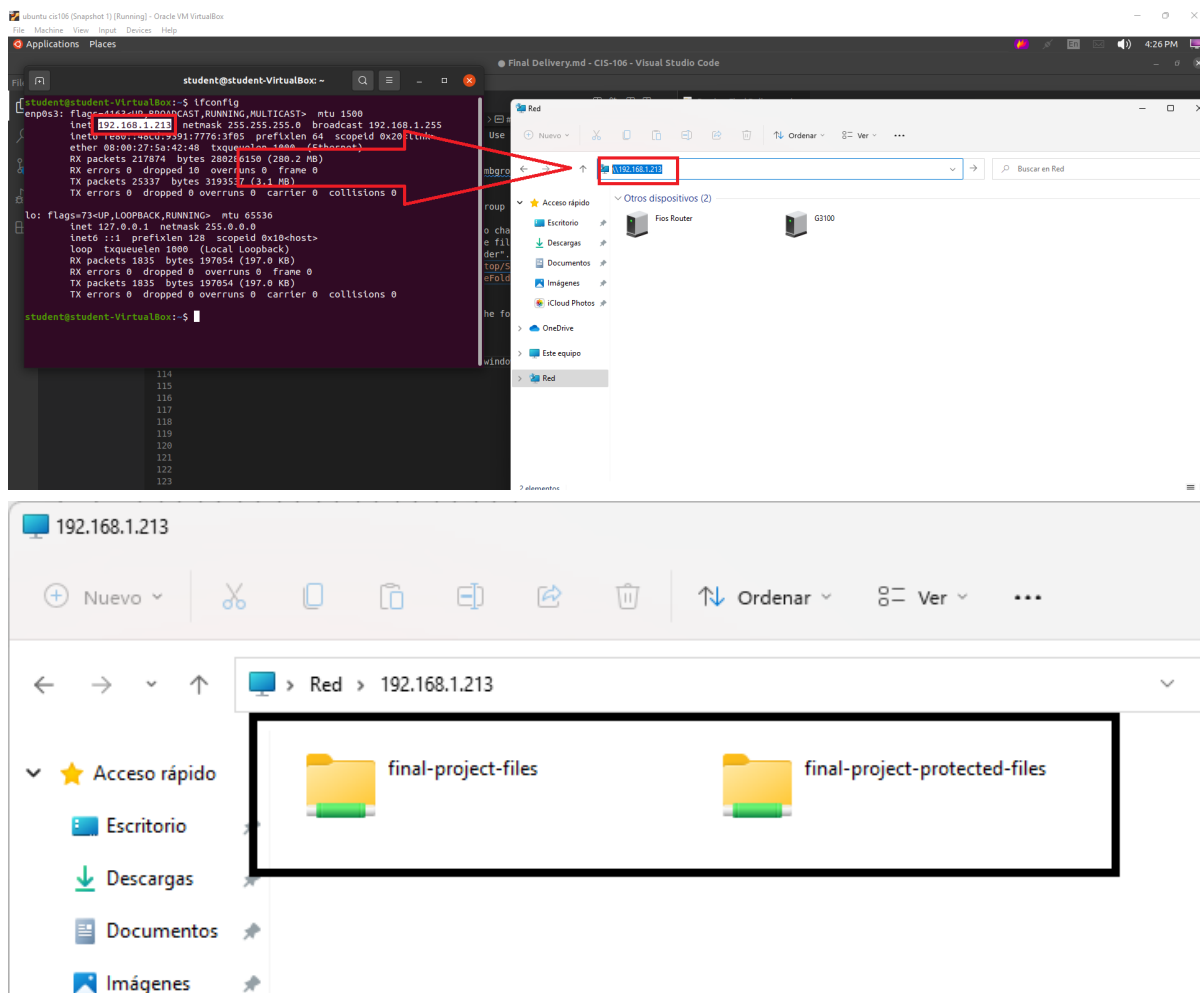

- Then , we are going to use the command "chown" to change the user and group permissions to the parent directory where the files are located. In my case the name of the directory is "ShareableFolder". `sudo chown -R smbuser:smbgroup`
`/home/student/Desktop/ShareableFolder sudo chmod -R g+w`
`/home/student/Desktop/ShareableFolder`

```
student@student-VirtualBox:~$ ls -l ~/Desktop/
total 4
drwxrwxr-x 4 smbuser smbgroup 4096 Nov 30 22:59 ShareableFolder
student@student-VirtualBox:~$ ls -l ~/Desktop/ShareableFolder/
total 8
drwxrwxr-x 2 smbuser smbgroup 4096 Nov 30 22:59 protected
drwxrwxr-x 3 smbuser smbgroup 4096 Nov 30 23:57 public
```

- After that , We are ready to turn on SAMBA using the following command. `sudo systemctl start smbd`

```
student@student-VirtualBox:~$ sudo systemctl start smbd
student@student-VirtualBox:~$ sudo systemctl status smbd
● smbd.service - Samba SMB Daemon
   Loaded: loaded (/lib/systemd/system/smbd.service; enabled; vendor preset:
   Active: active (running) since Sat 2021-12-18 16:23:26 EST; 2s ago
     Docs: man:smbd(8)
           man:samba(7)
           man:smb.conf(5)
   Process: 38704 ExecStartPre=/usr/share/samba/update-apparmor-samba-profile
   Main PID: 38708 (smbd)
   Status: "Ready to receive connections"
```

- In order to access to your SAMBA file server on a windows computer. You must identify your Local IP. Then , type it down in your file browser.

Final Quotes:

This project was challenging. It takes you deeper to group and user permissions. Also , it is a good tool when you want to share files between your laptop and your desktop computer. I actually used it the whole semester because i do not usually use my laptop at home, but all the files from different classes were there. Using samba, i was able to always share the files between my laptop and my computer.
